

Preliminary MaxEnt analysis

- The simple variable ranking approach assumed in the poster incorrectly predicts that the Reciprocalized Applicative ([[[Rt]A]R]) should attest a doubling output.
- This same problem arises in MaxEnt if we assume a 50/50 frequency distribution for both variable patterns: MaxEnt does not do a good job matching the probabilities. This is shown in Figure 1.

Figure 1: 50/50 frequency distribution in MaxEnt

[[[Rt]Rec]Caus]	Freq	Pred	[[[Rt]Rec]Appl]	Freq	Pred
CARP	.50	.33	CARP	.50	.69
Cyclic	.50	.53	Cyclic	.00	.00
Doubling	.00	.13	Doubling	.50	.28

- Various possible *uneven* frequency distributions yield a much better match between input frequencies and the frequencies predicted by MaxEnt. One such distribution is given in Figure 2 (full analysis in Figure 3 on the following page).

Figure 2: One possible frequency distribution

[[[Rt]Rec]Caus]	Freq	Pred	[[[Rt]Rec]Appl]	Freq	Pred
CARP	.60	.54	CARP	.80	.89
Cyclic	.40	.40	Cyclic	.00	.00
Doubling	.00	.05	Doubling	.20	.09

- I am not aware of any reports regarding the actual relative frequency of the respective variants within each of the two patterns.
- Therefore, we may be able to derive a *testable prediction* from the MaxEnt analysis about what (ranges of) frequencies we should observe in the actual data.
- Namely, we predict that the real attested frequencies should be the set of input frequencies that provide the best match to the MaxEnt predicted frequencies.
